Revisit 2 Review Log

Group No.:	Calculator Version Reviewed:	Date:
9	Prototype 1	2026-11-09

Use the role sheets and the Master Group Worksheet to summarize the group's main decisions. Do not copy every observation from the role sheets.

A Client Needs Update

Li Ming still needs to see his footprint for one teaching semester, which activities are counted, which are left out, and which number he can change to lower the result. This revisit adds two needs. He needs to see that the semester length is an assumption, not a fact from the shared profile, and he needs the headline to separate sourced kg CO_2 from unverified kg CO_2e.

B Review Findings and Decisions

Summarize the most important findings. Use specific evidence rather than copying the full role worksheets.

Finding 1

What We Found	Weekly and monthly activities are scaled by a fixed 18-week semester. The page does not let Li Ming change that number. If the semester is shorter, food and city travel should fall, while high-speed rail should stay the same.
Evidence and Role Code(s)	Prototype 1 stores the period as constants: 18 weeks, 4.5 months, and 126 electricity days. Metro kilometres and meal counts are multiplied by 18. High-speed rail is already entered per teaching semester. Role codes: C, U.
What We Decided to Do and Why	Add an editable field, "Weeks in a teaching semester", default 18. Weekly activities use this number. Monthly activities use 1 month = 4 weeks, so months equal weeks divided by 4. Electricity days equal weeks times 7. High-speed rail and clothing stay per semester. The note states that 18 weeks is an assumption. Reset returns the field to 18.

Finding 2

What We Found	The headline is written as kg CO_2e, but the total mixes units. Electricity and high-speed rail use sourced kg CO_2 factors. The other quantified items, including food, still use unverified kg CO_2e. With the default profile, beef or lamb is about 324 kg and fills the top suggestions, even though those per-meal factors have no meal weight.
Evidence and Role Code(s)	Prototype 1 cites electricity at 0.5737 kg CO_2/kWh and high-speed rail at 0.02709 kg CO_2/passenger·km. Food, metro, and ride-hailing remain marked "not yet verified". The ride-hailing suggestion also called 0.20 kg/km a per-passenger factor. Role codes: C, R.
What We Decided to Do and Why	Change the headline to a reported mixed total. Show sourced kg CO_2 and unverified kg CO_2e on separate lines. If a suggestion uses an unverified per-meal factor, say the comparison is illustrative because the profile gives no meal weight. State the ride-hailing factor as kg/km. Do not invent a meal weight, and do not add showers, parcels, clothing, or waste to the total.

C Priority Revisions

The final calculator addresses these two findings first: an editable teaching-semester length, then a mixed-unit result label with the suggestion caveat. No other scope was added.

D Post-review changes, 2026-11-10

Appended after the review session. The 2026-11-09 record above is unchanged.

Why this section exists	Between the review and the submission, the page was revised again on 2026-11-10. None of it changes the boundary or the categories, so the decision recorded in section C still holds. It is recorded here so the final calculator and this log describe the same file.
Food rows rebuilt (role code C)	Each food row is now meals per week × a portion in grams × a factor per kilogram of food, instead of one figure per meal. The four default portions are 100, 250, 400, and 400 g, which reproduce the previous per-meal values exactly: 324, 216, 72, and 36 kg. The default result is therefore unchanged.
The meal weight is now an input (role codes C, R)	Finding 2 said the profile gives no meal weight and that we should not invent one. The portion is now an editable field labelled as an assumption, so the weight is visible and can be changed rather than hidden inside a per-meal factor. This settles Finding 2 without asserting a weight as fact.
Presentation changed (role code U)	The page was restyled to match the slides, the copy was shortened, each step gained an icon, and each category on the results page links back to its step. No input, factor, or boundary was added or removed.
Test result, 2026-11-10	Default: 783.7 kg reported, food 648.0 kg, food mass 113.4 kg. Beef suggestion −159.3 kg to 624.4 kg; other meat −90.0 kg to 693.7 kg; electricity unchanged at −14.5 kg to 769.3 kg. The beef figure moved only because the portion is explicit: 27 meals × 100 g × (60 − 1) kg CO_2e/kg.
